# A Producer Library Interface to DWARF

David Anderson

#### 1. INTRODUCTION

This document describes an interface to libdwarf, a library of functions to provide creation of DWARF debugging information records, DWARF line number information, DWARF address range and pubnames information, weak names information, and DWARF frame description information.

## 1.2 Purpose and Scope

The purpose of this document is to propose a library of functions to create DWARF debugging information. Reading (consuming) of such records is discussed in a separate document.

The functions in this document have mostly been implemented at Silicon Graphics and are being used by the code generator to provide debugging information. Some functions (and support for some extensions) were provided by Sun Microsystems.

The focus of this document is the functional interface, and as such, implementation and optimization issues are intentionally ignored.

Error handling, error codes, and certain Libdwarf codes are discussed in the "A Consumer Library Interface to DWARF", which should be read (or at least skimmed) before reading this document.

However the general style of functions here in the producer librar is rather C-traditional with various types as return values (quite different from the consumer library interfaces). The style generally follows the style of the original DWARF1 reader proposed as an interface to DWARF. When the style of the reader interfaces was changed (1994) in the dwarf reader ( See the "Document History" section of "A Consumer Library Interface to DWARF") the interfaces here were not changed as it seemed like too much of a change for the two applications then using the interface! So this interface remains in the traditional C style of returning various data types with various (somewhat inconsistent) means of indicating failure.

## 1.3 Document History

This document originally prominently referenced "UNIX International Programming Languages Special Interest Group " (PLSIG). Both UNIX International and the affiliated Programming Languages Special Interest Group are defunct (UNIX is a registered trademark of UNIX System Laboratories, Inc. in the United States and other countries). Nothing except the general interface style is actually related to anything shown to the PLSIG (this document was open sourced with libdwarf in the mid 1990's).

See "http://www.dwarfstd.org" for information on current DWARF standards and committee activities.

#### 1.4 Definitions

DWARF debugging information entries (DIEs) are the segments of information placed in the .debug\_info and related sections by compilers, assemblers, and linkage editors that, in conjunction with line number entries, are necessary for symbolic source-level debugging. Refer to the document "DWARF Debugging Information Format" from UI PLSIG for a more complete description of these entries.

This document adopts all the terms and definitions in "DWARF Debugging Information Format" version 2. and the "A Consumer Library Interface to DWARF".

In addition, this document refers to Elf, the ATT/USL System V Release 4 object format. This is because the library was first developed for that object format. Hopefully the functions defined here can easily be applied to other object formats.

## 1.5 Overview

The remaining sections of this document describe a proposed producer (compiler or assembler) interface to *Libdwarf*, first by describing the purpose of additional types defined by the interface, followed by descriptions of the available operations. This document assumes you are thoroughly familiar with the information contained in the *DWARF Debugging Information Format* document, and "A Consumer Library Interface to DWARF".

The interface necessarily knows a little bit about the object format (which is assumed to be Elf). We make an attempt to make this knowledge as limited as possible. For example, *Libdwarf* does not do the writing of object data to the disk. The producer program does that.

# 1.6 Revision History

March 1993	Work on dwarf2 sgi producer draft begins			
March 1999	Adding a function to allow any number of trips through the dwarf_get_section_byt call.			
April 10 1999	Added support for assembler text output of dwarf (as when the output must pass through an assembler). Revamped internals for better performance and simpler provision for differences in ABI.			
Sep 1, 1999	Added support for little- and cross- endian debug info creation.			
May 7 2007	This library interface now cleans up, deallocating all memory it uses (the application simply calls dwarf_producer_finish(dbg)).			

# 2. Type Definitions

## 2.1 General Description

The *libdwarf.h* header file contains typedefs and preprocessor definitions of types and symbolic names used to reference objects of *Libdwarf*. The types defined by typedefs contained in *libdwarf.h* all use the convention of adding *Dwarf\_* as a prefix to indicate that they refer to objects used by Libdwarf. The prefix *Dwarf\_P\_* is used for objects referenced by the *Libdwarf* Producer when there are similar but distinct objects used by the Consumer.

# 2.2 Namespace issues

Application programs should avoid creating names beginning with Dwarf\_ dwarf\_ or DW\_ as these are reserved to dwarf and libdwarf.

### 3. libdwarf and Elf and relocations

Much of the description below presumes that Elf is the object format in use. The library is probably usable with other object formats that allow arbitrary sections to be created.

## 3.1 binary or assembler output

With DW\_DLC\_STREAM\_RELOCATIONS (see below) it is assumed that the calling app will simply write the streams and relocations directly into an Elf file, without going through an assembler.

With DW\_DLC\_SYMBOLIC\_RELOCATIONS the calling app must either A) generate binary relocation streams and write the generated debug information streams and the relocation streams direct to an elf file or B) generate assembler output text for an assembler to read and produce an object file.

With case B) the libdwarf-calling application must use the relocation information to change points of each binary stream into references to symbolic names. It is necessary for the assembler to be willing to accept and generate relocations for references from arbitrary byte boundaries. For example:

.data 0a0bcc #producing 3 bytes of data.
.word mylabel #producing a reference
.word endlabel - startlable #producing absolute length

## 3.2 libdwarf relationship to Elf

When the documentation below refers to 'an elf section number' it is really only dependent on getting (via the callback function passed by the caller of dwarf\_producer\_init()) a sequence of integers back (with 1 as the lowest).

When the documentation below refers to 'an Elf symbol index' it is really dependent on Elf symbol numbers only if DW\_DLC\_STREAM\_RELOCATIONS are being generated (see below). With DW\_DLC\_STREAM\_RELOCATIONS the library is generating Elf relocations and the section numbers in binary form so the section numbers and symbol indices must really be Elf (or elf-like) numbers.

With DW\_DLC\_SYMBOLIC\_RELOCATIONS the values passed as symbol indexes can be any integer set or even pointer set. All that libdwarf assumes is that where values are unique they get unique values. Libdwarf does not generate any kind of symbol table from the numbers and does not check their uniqueness or lack thereof.

#### 3.3 libdwarf and relocations

With DW\_DLC\_SYMBOLIC\_RELOCATIONS libdwarf creates binary streams of debug information and arrays of relocation information describing the necessary relocation. The Elf section numbers and symbol numbers appear nowhere in the binary streams. Such appear only in the relocation information and the passed-back information from calls requesting the relocation information. As a consequence, the 'symbol indices' can be any pointer or integer value as the caller must arrange that the output deal with relocations.

With DW\_DLC\_STREAM\_RELOCATIONS all the relocations are directly created by libdwarf as binary streams (libdwarf only creates the streams in memory, it does not write them to disk).

## 3.4 symbols, addresses, and offsets

The following applies to calls that pass in symbol indices, addresses, and offsets, such as dwarf\_add\_AT\_targ\_address() dwarf\_add\_arange\_b() and dwarf\_add\_frame\_fde\_b().

With DW\_DLC\_STREAM\_RELOCATIONS a passed in address is one of: a) a section offset and the (non-global) symbol index of a section symbol. b) A symbol index (global symbol) and a zero offset.

With DW\_DLC\_SYMBOLIC\_RELOCATIONS the same approach can be used, or, instead, a passed in address may be c) a symbol handle and an offset. In this case, since it is up to the calling app to generate binary relocations (if appropriate) or to turn the binary stream into a text stream (for input to an assembler, if appropriate) the application has complete control of the interpretation of the symbol handles.

## 4. Memory Management

Several of the functions that comprise the *Libdwarf* producer interface dynamically allocate values and some return pointers to those spaces. The dynamically allocated spaces can not be reclaimed (and must not be freed) except by dwarf\_producer\_finish(dbg).

All data for a particular Dwarf\_P\_Debug descriptor is separate from the data for any other Dwarf\_P\_Debug descriptor in use in the library-calling application.

#### 4.1 Read-only Properties

All pointers returned by or as a result of a *Libdwarf* call should be assumed to point to read-only memory. Except as defined by this document, the results are undefined for *Libdwarf* clients that attempt to write to a region pointed to by a return value from a *Libdwarf* call.

#### 4.2 Storage Deallocation

Calling dwarf\_producer\_finish(dbg) frees all the space, and invalidates all pointers returned from Libdwarf functions on or descended from dbg).

## 5. Functional Interface

This section describes the functions available in the *Libdwarf* library. Each function description includes its definition, followed by a paragraph describing the function's operation.

The functions may be categorized into groups: initialization and termination operations, debugging information entry creation, Elf section callback function, attribute creation, expression creation, line number creation, fast-access (aranges) creation, fast-access (pubnames) creation, fast-access (weak names) creation, macro information creation, low level (.debug\_frame) creation, and location list (.debug\_loc) creation.

The following sections describe these functions.

## 5.1 Initialization and Termination Operations

These functions setup Libdwarf to accumulate debugging information for an object, usually a compilation-unit, provided by the producer. The actual addition of information is done by functions in the other sections of this document. Once all the information has been added, functions from this section are used to transform the information to appropriate byte streams, and help to write out the byte streams to disk.

Typically then, a producer application would create a Dwarf\_P\_Debug descriptor to gather debugging information for a particular compilation-unit using dwarf\_producer\_init(). The producer application would use this Dwarf\_P\_Debug descriptor to accumulate debugging information for this object using functions from other sections of this document. Once all the information had been added, it would call dwarf\_transform\_to\_disk\_form() to convert the accumulated information into byte streams in accordance with the DWARF standard. The application would then repeatedly call dwarf\_get\_section\_bytes() for each of the .debug\_\* created. This gives the producer information about the data bytes to be written to disk. At this point, the producer would release all resource used by Libdwarf for this object by calling dwarf\_producer\_finish().

It is also possible to create assembler-input character streams from the byte streams created by this library. This feature requires slightly different interfaces than direct binary output. The details are mentioned in the text.

#### **5.1.1** dwarf\_producer\_init()

The function dwarf\_producer\_init() returns a new Dwarf\_P\_Debug descriptor that can be used to add Dwarf information to the object. On error it returns DW\_DLV\_BADADDR. flags determine whether the target object is 64-bit or 32-bit. func is a pointer to a function called-back from Libdwarf whenever Libdwarf needs to create a new object section (as it will for each .debug\_\* section and related relocation section). errhand is a pointer to a function that will be used for handling errors detected by Libdwarf. errarg is the default error argument used by the function pointed to by errhand.

The flags values are as follows:

DW\_DLC\_WRITE is required. The values DW\_DLC\_READ DW\_DLC\_RDWR are not supported by

the producer and must not be passed.

If DW\_DLC\_SIZE\_64 is not ORed into flags then DW\_DLC\_SIZE\_32 is assumed. Oring in both is an error.

If DW\_DLC\_OFFSET\_SIZE\_64 is not ORed into flags then 64 bit offsets (as defined in the 1999 DWARF3) may be used (see next paragraph) to generate DWARF (if and only if DW\_DLC\_SIZE\_64 is also ORed into flags).

If HAVE\_STRICT\_32BIT\_OFFSET is set at configure time only 32bit DWARF offsets are generated (use configure option --enable-dwarf-format-strict-32bit) and DW\_DLC\_OFFSET\_SIZE\_64 is ignored. If HAVE\_SGI\_IRIX\_OFFSETS is set at configure time SGI IRIX offsets (standard 32bit, a special 64bit offset for 64bit address objects) are generated (use configure option --enable-dwarf-format-sgi-irix) and DW\_DLC\_OFFSET\_SIZE\_64 is ignored. If neither HAVE\_STRICT\_32BIT\_OFFSET nor HAVE\_SGI\_IRIX\_OFFSETS is set at configure time then standard offset sizes are used ( and HAVE\_DWARF2\_99\_EXTENSION is set) and DW\_DLC\_OFFSET\_SIZE\_64 is honored.

If DW\_DLC\_ISA\_IA64 is not ORed into flags then DW\_DLC\_ISA\_MIPS is assumed. Oring in both is an error.

If DW\_DLC\_TARGET\_BIGENDIAN is not ORed into flags then endianness the same as the host is assumed.

If DW\_DLC\_TARGET\_LITTLEENDIAN is not ORed into flags then endianness the same as the host is assumed.

If both DW\_DLC\_TARGET\_LITTLEENDIAN and DW\_DLC\_TARGET\_BIGENDIAN are or-d in it is an error.

Either one of two output forms is specifiable:  $DW\_DLC\_STREAM\_RELOCATIONS$  or  $DW\_DLC\_SYMBOLIC\_RELOCATIONS$ .

The default is DW\_DLC\_STREAM\_RELOCATIONS . The DW\_DLC\_STREAM\_RELOCATIONS are relocations in a binary stream (as used in a MIPS Elf object).

The DW\_DLC\_SYMBOLIC\_RELOCATIONS are the same relocations but expressed in an array of structures defined by libdwarf, which the caller of the relevant function (see below) must deal with appropriately. This method of expressing relocations allows the producer-application to easily produce assembler text output of debugging information.

If DW\_DLC\_SYMBOLIC\_RELOCATIONS is ORed into flags then relocations are returned not as streams but through an array of structures.

The function func must be provided by the user of this library. Its prototype is:

```
typedef int (*Dwarf_Callback_Func)(
    char* name,
    int
                         size,
    Dwarf Unsigned
                         type,
   Dwarf_Unsigned
                         flags,
    Dwarf_Unsigned
                         link,
   Dwarf_Unsigned
                         info,
    int*
                         sect_name_index,
    int*
                         error)
```

For each section in the object file that libdwarf needs to create, it calls this function once, passing in the section name, the section type, the section flags, the link field, and the info field. For an Elf object file these values should be appropriate Elf section header values. For example, for relocation callbacks, the link field is supposed to be set (by the app) to the index of the symtab section (the link field passed through the callback must be ignored by the app). And, for relocation callbacks, the info field is passed as the elf section number of the section the relocations apply to.

On success the user function should return the Elf section number of the newly created Elf section.

On success, the function should also set the integer pointed to by sect\_name\_index to the Elf symbol number assigned in the Elf symbol table of the new Elf section. This symbol number is needed with relocations dependent on the relocation of this new section. Because "int \*" is not guaranteed to work with elf 'symbols' that are really pointers, It is better to use the dwarf producer init b() interface.

For example, the .debug\_line section's third data element (in a compilation unit) is the offset from the beginning of the .debug\_info section of the compilation unit entry for this .debug\_line set. The relocation entry in .rel.debug\_line for this offset must have the relocation symbol index of the symbol .debug\_info returned by the callback of that section-creation through the pointer sect\_name\_index.

On failure, the function should return -1 and set the error integer to an error code.

Nothing in libdwarf actually depends on the section index returned being a real Elf section. The Elf section is simply useful for generating relocation records. Similarly, the Elf symbol table index returned through the sect\_name\_index must simply be an index that can be used in relocations against this section. The application will probably want to note the values passed to this function in some form, even if no Elf file is being produced.

## **5.1.2** dwarf\_producer\_init\_b()

The function dwarf\_producer\_init\_b() is the same as dwarf\_producer\_init() except that the callback function uses Dwarf\_Unsigned rather than int as the type of the symbol-index returned to libdwarf through the pointer argument (see below).

The flags values are as follows:

DW\_DLC\_WRITE is required. The values DW\_DLC\_READ DW\_DLC\_RDWR are not supported by the producer and must not be passed.

If DW\_DLC\_SIZE\_64 is not ORed into flags then DW\_DLC\_SIZE\_32 is assumed. Oring in

both is an error.

If DW\_DLC\_ISA\_IA64 is not ORed into flags then DW\_DLC\_ISA\_MIPS is assumed. Oring in both is an error.

Either one of two output forms are specifiable:  $DW\_DLC\_STREAM\_RELOCATIONS$  or  $DW\_DLC\_SYMBOLIC\_RELOCATIONS$  .  $dwarf\_producer\_init\_b()$  is usable with either output form.

Either one of two output forms is specifiable:  $DW\_DLC\_STREAM\_RELOCATIONS$  or  $DW\_DLC\_SYMBOLIC\_RELOCATIONS$ .

The default is DW\_DLC\_STREAM\_RELOCATIONS. The DW\_DLC\_STREAM\_RELOCATIONS are relocations in a binary stream (as used in a MIPS Elf object).

DW\_DLC\_SYMBOLIC\_RELOCATIONS are ORed into flags to cause the same relocations to be expressed in an array of structures defined by libdwarf, which the caller of the relevant function (see below) must deal with appropriately. This method of expressing relocations allows the producer-application to easily produce assembler text output of debugging information.

The function func must be provided by the user of this library. Its prototype is:

```
typedef int (*Dwarf_Callback_Func_b)(
    char* name,
    int
                         size,
    Dwarf Unsigned
                         type,
   Dwarf_Unsigned
                         flags,
    Dwarf_Unsigned
                         link,
    Dwarf_Unsigned
                         info,
    Dwarf_Unsigned*
                         sect_name_index,
    int*
                         error)
```

For each section in the object file that libdwarf needs to create, it calls this function once, passing in the section name, the section type, the section flags, the link field, and the info field. For an Elf object file these values should be appropriate Elf section header values. For example, for relocation callbacks, the link field is supposed to be set (by the app) to the index of the symtab section (the link field passed through the callback must be ignored by the app). And, for relocation callbacks, the info field is passed as the elf section number of the section the relocations apply to.

On success the user function should return the Elf section number of the newly created Elf section.

On success, the function should also set the integer pointed to by sect\_name\_index to the Elf symbol number assigned in the Elf symbol table of the new Elf section. This symbol number is needed with relocations dependent on the relocation of this new section.

For example, the .debug\_line section's third data element (in a compilation unit) is the offset from the beginning of the .debug\_info section of the compilation unit entry for this .debug\_line set. The relocation entry in .rel.debug\_line for this offset must have the relocation symbol index of the symbol .debug\_info returned by the callback of that section-creation through the pointer sect name index.

On failure, the function should return -1 and set the error integer to an error code.

Nothing in libdwarf actually depends on the section index returned being a real Elf section. The Elf section is simply useful for generating relocation records. Similarly, the Elf symbol table index returned through the sect\_name\_index must simply be an index that can be used in relocations against this section. The application will probably want to note the values passed to this function in some form, even if no Elf file is

being produced.

Note that the Dwarf\_Callback\_Func\_b() form passes back the sect\_name\_index as a Dwarf\_Unsigned. This is guaranteed large enough to hold a pointer. (the other functional interfaces have versions with the 'symbol index' as a Dwarf Unsigned too. See below).

If DW\_DLC\_SYMBOLIC\_RELOCATIONS is in use, then the symbol index is simply an arbitrary value (from the point of view of libdwarf) so the caller can put anything in it: a normal elf symbol index, a pointer to a struct (with arbitrary contents) (the caller must cast to/from Dwarf\_Unsigned as appropriate), or some other kind of pointer or value. The values show up in the output of dwarf\_get\_relocation\_info() (described below) and are not emitted anywhere else.

#### **5.1.3** dwarf\_transform\_to\_disk\_form()

The function dwarf\_transform\_to\_disk\_form() does the actual conversion of the Dwarf information provided so far, to the form that is normally written out as Elf sections. In other words, once all DWARF information has been passed to Libdwarf, call dwarf\_transform\_to\_disk\_form() to transform all the accumulated data into byte streams. This includes turning relocation information into byte streams (and possibly relocation arrays). This function does not write anything to disk. If successful, it returns a count of the number of Elf sections ready to be retrieved (and, normally, written to disk). In case of error, it returns DW\_DLV\_NOCOUNT.

#### **5.1.4** dwarf\_get\_section\_bytes()

The function <code>dwarf\_get\_section\_bytes()</code> must be called repetitively, with the index <code>dwarf\_section</code> starting at 0 and continuing for the number of sections returned by <code>dwarf\_transform\_to\_disk\_form()</code>. It returns <code>NULL</code> to indicate that there are no more sections of <code>Dwarf</code> information. For each non-<code>NULL</code> return, the return value points to <code>\*length</code> bytes of data that are normally added to the output object in <code>Elf</code> section <code>\*elf\_section</code> by the producer application. It is illegal to call these in any order other than 0 through <code>N-1</code> where <code>N</code> is the number of dwarf sections returned by <code>dwarf\_transform\_to\_disk\_form()</code>. The <code>dwarf\_section</code> number is actually ignored: the data is returned as if the caller passed in the correct <code>dwarf\_section</code> numbers in the required sequence. The <code>error</code> argument is not used.

There is no requirement that the section bytes actually be written to an elf file. For example, consider the .debug\_info section and its relocation section (the call back function would resulted in assigning 'section' numbers and the link field to tie these together (.rel.debug\_info would have a link to .debug\_info). One could examine the relocations, split the .debug\_info data at relocation boundaries, emit byte streams (in hex) as assembler output, and at each relocation point, emit an assembler directive with a symbol name for the assembler. Examining the relocations is awkward though. It is much better to use

```
dwarf_get_section_relocation_info()
```

The memory space of the section byte stream is freed by the dwarf\_producer\_finish() call (or would be if the dwarf\_producer\_finish() was actually correct), along with all the other space in use with that Dwarf\_P\_Debug.

#### 5.1.5 dwarf\_get\_relocation\_info\_count()

The function dwarf\_get\_relocation\_info() returns, through the pointer count\_of\_relocation\_sections, the number of times that dwarf\_get\_relocation\_info() should be called.

The function dwarf\_get\_relocation\_info() returns DW\_DLV\_OK if the call was successful (the count\_of\_relocation\_sections is therefore meaningful, though count\_of\_relocation\_sections could be zero).

\*drd\_buffer\_version is the value 2. If the structure pointed to by the \*reldata\_buffer changes this number will change. The application should verify that the number is the version it understands (that it matches the value of DWARF\_DRD\_BUFFER\_VERSION (from libdwarf.h)). The value 1 version was never used in production MIPS libdwarf (version 1 did exist in source).

It returns DW\_DLV\_NO\_ENTRY if count\_of\_relocation\_sections is not meaningful because DW\_DLC\_SYMBOLIC\_RELOCATIONS was not passed in the dwarf\_producer\_init() (or dwarf\_producer\_init\_b() ) call.

It returns DW\_DLV\_ERROR if there was an error, in which case count\_of\_relocation\_sections is not meaningful.

## **5.1.6** dwarf\_get\_relocation\_info()

The function dwarf\_get\_relocation\_info() should normally be called repetitively, for the number of relocation sections that dwarf get relocation info count() indicated exist.

It returns DW\_DLV\_OK to indicate that valid values are returned through the pointer arguments. The error argument is not set.

It returns DW\_DLV\_NO\_ENTRY if there are no entries (the count of relocation arrays is zero.). The error argument is not set.

It returns DW\_DLV\_ERROR if there is an error. Calling dwarf\_get\_relocation\_info() more than the number of times indicated by dwarf\_get\_relocation\_info\_count() (without an intervening call to dwarf\_reset\_section\_bytes() ) results in a return of DW\_DLV\_ERROR once past the valid count. The error argument is set to indicate the error.

Now consider the returned-through-pointer values for DW\_DLV\_OK.

\*elf\_section\_index is the 'elf section index' of the section implied by this group of relocations.

\*elf\_section\_index\_link is the section index of the section that these relocations apply to.

\*relocation\_buffer\_count is the number of array entries of relocation information in the array pointed to by \*reldata\_buffer.

\*reldata\_buffer points to an array of 'struct Dwarf\_Relocation\_Data\_s' structures.

The version 2 array information is as follows:

```
enum Dwarf_Rel_Type {dwarf_drt_none,
         dwarf_drt_data_reloc,
         dwarf drt segment rel,
         dwarf_drt_first_of_length_pair,
         dwarf drt second of length pair
typedef struct Dwarf_Relocation_Data_s * Dwarf_Relocation_Data;
struct Dwarf Relocation Data s {
                      drd_type; /* contains Dwarf_Rel_Type */
    unsigned char
                      drd_length; /* typically 4 or 8 */
    unsigned char
                        drd offset; /* where the data to reloc is */
    Dwarf Unsigned
    Dwarf Unsigned
                        drd symbol index;
};
```

The Dwarf\_Rel\_Type enum is encoded (via casts if necessary) into the single unsigned chard\_type field to control the space used for this information (keep the space to 1 byte).

The unsigned char drd\_length field holds the size in bytes of the field to be relocated. So for elf32 object formats with 32 bit apps, drd\_length will be 4. For objects with MIPS -64 contents, drd\_length will be 8. For some dwarf 64 bit environments, such as ia64, drd\_length is 4 for some relocations (file offsets, for example) and 8 for others (run time addresses, for example).

If drd\_type is dwarf\_drt\_none, this is an unused slot and it should be ignored.

If drd\_type is dwarf\_drt\_data\_reloc this is an ordinary relocation. The relocation type means either (R\_MIPS\_64) or (R\_MIPS\_32) (or the like for the particular ABI. drd\_length gives the length of the field to be relocated. drd\_offset is an offset (of the value to be relocated) in the section this relocation stuff is linked to. drd\_symbol\_index is the symbol index (if elf symbol indices were provided) or the handle to arbitrary information (if that is what the caller passed in to the relocation-creating dwarf calls) of the symbol that the relocation is relative to.

When drd type is dwarf drt first of length pair the next data record will be

drt\_second\_of\_length\_pair and the drd\_offset of the two data records will match. The relevant 'offset' in the section this reloc applies to should contain a symbolic pair like

```
. word \quad second\_symbol - first\_symbol
```

to generate a length. drd length gives the length of the field to be relocated.

drt\_segment\_rel means (R\_MIPS\_SCN\_DISP) is the real relocation (R\_MIPS\_SCN\_DISP applies to exception tables and this part may need further work). drd\_length gives the length of the field to be relocated.

The memory space of the section byte stream is freed by the dwarf\_producer\_finish() call (or would be if the dwarf\_producer\_finish() was actually correct), along with all the other space in use with that Dwarf\_P\_Debug.

### **5.1.7** dwarf\_reset\_section\_bytes()

The function dwarf\_reset\_section\_bytes() is used to reset the internal information so that dwarf\_get\_section\_bytes() will begin (on the next call) at the initial dwarf section again. It also resets so that calls to dwarf\_get\_relocation\_info() will begin again at the initial array of relocation information.

Some dwarf producers need to be able to run through the dwarf\_get\_section\_bytes() and/or the dwarf\_get\_relocation\_info() calls more than once and this call makes additional passes possible. The set of Dwarf\_Ptr values returned is identical to the set returned by the first pass. It is acceptable to call this before finishing a pass of dwarf\_get\_section\_bytes() or dwarf\_get\_relocation\_info() calls. No errors are possible as this just resets some internal pointers. It is unwise to call this before dwarf\_transform\_to\_disk\_form() has been called.

#### **5.1.8** dwarf\_producer\_finish()

The function <code>dwarf\_producer\_finish()</code> should be called after all the bytes of data have been copied somewhere (normally the bytes are written to disk). It frees all dynamic space allocated for <code>dbg</code>, include space for the structure pointed to by <code>dbg</code>. This should not be called till the data have been copied or written to disk or are no longer of interest. It returns non-zero if <code>successful</code>, and <code>DW\_DLV\_NOCOUNT</code> if there is an error.

## **5.2 Debugging Information Entry Creation**

The functions in this section add new DIEs to the object, and also the relationships among the DIE to be specified by linking them up as parents, children, left or right siblings of each other. In addition, there is a function that marks the root of the graph thus created.

#### **5.2.1** dwarf\_add\_die\_to\_debug()

The function dwarf\_add\_die\_to\_debug() indicates to Libdwarf the root DIE of the DIE graph that has been built so far. It is intended to mark the compilation-unit DIE for the object represented by dbg. The root DIE is specified by first\_die.

It returns 0 on success, and DW\_DLV\_NOCOUNT on error.

#### 5.2.2 dwarf new die()

The function dwarf\_new\_die() creates a new DIE with its parent, child, left sibling, and right sibling DIEs specified by parent, child, left\_sibling, and right\_sibling, respectively. There is no requirement that all of these DIEs be specified, i.e. any of these descriptors may be NULL. If none is specified, this will be an isolated DIE. A DIE is transformed to disk form by dwarf\_transform\_to\_disk\_form() only if there is a path from the DIE specified by dwarf\_add\_die\_to\_debug to it. This function returns DW\_DLV\_BADADDR on error.

new\_tag is the tag which is given to the new DIE. parent, child, left\_sibling, and right\_sibling are pointers to establish links to existing DIEs. Only one of parent, child, left\_sibling, and right\_sibling may be non-NULL. If parent (child) is given, the DIE is linked into the list after (before) the DIE pointed to. If left\_sibling (right\_sibling) is given, the DIE is linked into the list after (before) the DIE pointed to.

To add attributes to the new DIE, use the Attribute Creation functions defined in the next section.

#### 5.2.3 dwarf die link()

The function dwarf\_die\_link() links an existing DIE described by the given die to other existing DIEs. The given die can be linked to a parent DIE, a child DIE, a left sibling DIE, or a right sibling DIE by specifying non-NULL parent, child, left\_sibling, and right\_sibling Dwarf\_P\_Die descriptors. It returns the given Dwarf\_P\_Die descriptor, die, on success, and DW\_DLV\_BADADDR on error.

Only one of parent, child, left\_sibling, and right\_sibling may be non-NULL. If parent (child) is given, the DIE is linked into the list after (before) the DIE pointed to. If left\_sibling (right\_sibling) is given, the DIE is linked into the list after (before) the DIE pointed to. Non-NULL links overwrite the corresponding links the given die may have had before the call to dwarf die link().

#### **5.3 Attribute Creation**

The functions in this section add attributes to a DIE. These functions return a Dwarf\_P\_Attribute descriptor that represents the attribute added to the given DIE. In most cases the return value is only useful to determine if an error occurred.

Some of the attributes have values that are relocatable. They need a symbol with respect to which the linker will perform relocation. This symbol is specified by means of an index into the Elf symbol table for the object (of course, the symbol index can be more general than an index).

#### **5.3.1** dwarf\_add\_AT\_location\_expr()

The function dwarf\_add\_AT\_location\_expr() adds the attribute specified by attr to the DIE descriptor given by ownerdie. The attribute should be one that has a location expression as its value. The location expression that is the value is represented by the Dwarf\_P\_Expr descriptor loc\_expr. It returns the Dwarf\_P\_Attribute descriptor for the attribute given, on success. On error it returns DW\_DLV\_BADADDR.

#### 5.3.2 dwarf\_add\_AT\_name()

The function dwarf\_add\_AT\_name() adds the string specified by name as the value of the DW\_AT\_name attribute for the given DIE, ownerdie. It returns the Dwarf\_P\_attribute descriptor for the DW\_AT\_name attribute on success. On error, it returns DW\_DLV\_BADADDR.

## 5.3.3 dwarf\_add\_AT\_comp\_dir()

The function dwarf\_add\_AT\_comp\_dir() adds the string given by current\_working\_directory as the value of the DW\_AT\_comp\_dir attribute for the DIE described by the given ownerdie. It returns the Dwarf\_P\_Attribute for this attribute on success. On error, it returns DW\_DLV\_BADADDR.

#### **5.3.4** dwarf\_add\_AT\_producer()

The function dwarf\_add\_AT\_producer() adds the string given by producer\_string as the value of the DW\_AT\_producer attribute for the DIE given by ownerdie. It returns the Dwarf\_P\_Attribute descriptor representing this attribute on success. On error, it returns DW\_DLV\_BADADDR.

## 5.3.5 dwarf\_add\_AT\_const\_value\_signedint()

The function dwarf\_add\_AT\_const\_value\_signedint() adds the given Dwarf\_Signed value signed\_value as the value of the DW\_AT\_const\_value attribute for the DIE described by the given ownerdie. It returns the Dwarf\_P\_Attribute descriptor for this attribute on success. On error, it returns DW\_DLV\_BADADDR.

## **5.3.6** dwarf\_add\_AT\_const\_value\_unsignedint()

The function dwarf\_add\_AT\_const\_value\_unsignedint() adds the given Dwarf\_Unsigned value unsigned\_value as the value of the DW\_AT\_const\_value attribute for the DIE described by the given ownerdie. It returns the Dwarf\_P\_Attribute descriptor for this attribute on success. On error, it returns DW\_DLV\_BADADDR.

### **5.3.7** dwarf\_add\_AT\_const\_value\_string()

The function dwarf\_add\_AT\_const\_value\_string() adds the string value given by string\_value as the value of the DW\_AT\_const\_value attribute for the DIE described by the given ownerdie. It returns the Dwarf\_P\_Attribute descriptor for this attribute on success. On error, it returns DW\_DLV\_BADADDR.

#### 5.3.8 dwarf add AT targ address()

The function dwarf\_add\_AT\_targ\_address() adds an attribute that belongs to the "address" class to the die specified by ownerdie. The attribute is specified by attr, and the object that the DIE belongs to is specified by dbg. The relocatable address that is the value of the attribute is specified by pc\_value. The symbol to be used for relocation is specified by the sym\_index, which is the index of the symbol in the Elf symbol table.

It returns the Dwarf\_P\_Attribute descriptor for the attribute on success, and DW\_DLV\_BADADDR on error.

### 5.3.9 dwarf\_add\_AT\_targ\_address\_b()

The function dwarf\_add\_AT\_targ\_address\_b() is identical to dwarf\_add\_AT\_targ\_address\_b() except that sym\_index() is guaranteed to be large enough that it can contain a pointer to arbitrary data (so the caller can pass in a real elf symbol index, an arbitrary number, or a pointer to arbitrary data). The ability to pass in a pointer through sym\_index() is only usable with DW\_DLC\_SYMBOLIC\_RELOCATIONS.

The pc\_value is put into the section stream output and the sym\_index is applied to the relocation information.

Do not use this function for attr DW\_AT\_high\_pc if the value to be recorded is an offset (not a pc) [ use dwarf\_add\_AT\_unsigned\_const() (for example) instead].

#### **5.3.10** dwarf\_add\_AT\_dataref()

This is very similar to dwarf\_add\_AT\_targ\_address\_b() but results in a different FORM (results in DW\_FORM\_data4 or DW\_FORM\_data8).

Useful for adding relocatable addresses in location lists.

sym\_index() is guaranteed to be large enough that it can contain a pointer to arbitrary data (so the caller can pass in a real elf symbol index, an arbitrary number, or a pointer to arbitrary data). The ability to pass in a pointer through sym index() is only usable with DW DLC SYMBOLIC RELOCATIONS.

The pc\_value is put into the section stream output and the sym\_index is applied to the relocation information.

Do not use this function for DW\_AT\_high\_pc, use dwarf\_add\_AT\_unsigned\_const() [ (for example) if the value to be recorded is an offset of DW\_AT\_low\_pc] or dwarf\_add\_AT\_targ\_address\_b() [ if the value to be recorded is an address].

### **5.3.11** dwarf\_add\_AT\_ref\_address()

This is very similar to dwarf\_add\_AT\_targ\_address\_b() but results in a different FORM (results in DW FORM ref addr being generated).

Useful for DW\_AT\_type and DW\_AT\_import attributes.

sym\_index() is guaranteed to be large enough that it can contain a pointer to arbitrary data (so the caller can pass in a real elf symbol index, an arbitrary number, or a pointer to arbitrary data). The ability to pass in a pointer through sym\_index() is only usable with DW\_DLC\_SYMBOLIC\_RELOCATIONS.

The pc\_value is put into the section stream output and the sym\_index is applied to the relocation information.

Do not use this function for DW\_AT\_high\_pc.

#### 5.3.12 dwarf add AT unsigned const()

The function dwarf\_add\_AT\_unsigned\_const() adds an attribute with a Dwarf\_Unsigned value belonging to the "constant" class, to the DIE specified by ownerdie. The object that the DIE belongs to is specified by dbg. The attribute is specified by attr, and its value is specified by value.

It returns the Dwarf\_P\_Attribute descriptor for the attribute on success, and DW\_DLV\_BADADDR on error.

#### **5.3.13** dwarf\_add\_AT\_signed\_const()

The function dwarf\_add\_AT\_signed\_const() adds an attribute with a Dwarf\_Signed value belonging to the "constant" class, to the DIE specified by ownerdie. The object that the DIE belongs to is specified by dbg. The attribute is specified by attr, and its value is specified by value.

It returns the Dwarf\_P\_Attribute descriptor for the attribute on success, and DW\_DLV\_BADADDR on error.

#### **5.3.14** dwarf\_add\_AT\_reference()

The function dwarf\_add\_AT\_reference() adds an attribute with a value that is a reference to another DIE in the same compilation-unit to the DIE specified by ownerdie. The object that the DIE belongs to is specified by dbg. The attribute is specified by attr, and the other DIE being referred to is specified by otherdie.

This cannot generate DW FORM ref addr references to DIEs in other compilation units.

It returns the Dwarf\_P\_Attribute descriptor for the attribute on success, and DW\_DLV\_BADADDR on error.

## 5.3.15 dwarf\_add\_AT\_flag()

The function dwarf\_add\_AT\_flag() adds an attribute with a Dwarf\_Small value belonging to the "flag" class, to the DIE specified by ownerdie. The object that the DIE belongs to is specified by dbg. The attribute is specified by attr, and its value is specified by flag.

It returns the Dwarf\_P\_Attribute descriptor for the attribute on success, and DW\_DLV\_BADADDR on error.

#### 5.3.16 dwarf add AT string()

The function dwarf\_add\_AT\_string() adds an attribute with a value that is a character string to the DIE specified by ownerdie. The object that the DIE belongs to is specified by dbg. The attribute is specified by attr, and its value is pointed to by string.

It returns the Dwarf\_P\_Attribute descriptor for the attribute on success, and DW\_DLV\_BADADDR on error.

## **5.4 Expression Creation**

The following functions are used to convert location expressions into blocks so that attributes with values that are location expressions can store their values as a DW\_FORM\_blockn value. This is for both .debug\_info and .debug\_loc expression blocks.

To create an expression, first call dwarf\_new\_expr() to get a Dwarf\_P\_Expr descriptor that can be used to build up the block containing the location expression. Then insert the parts of the expression in prefix order (exactly the order they would be interpreted in in an expression interpreter). The bytes of the expression are then built-up as specified by the user.

## 5.4.1 dwarf\_new\_expr()

The function dwarf\_new\_expr() creates a new expression area in which a location expression stream can be created. It returns a Dwarf\_P\_Expr descriptor that can be used to add operators to build up a location expression. It returns NULL on error.

#### 5.4.2 dwarf\_add\_expr\_gen()

```
Dwarf_Unsigned dwarf_add_expr_gen(
          Dwarf_P_Expr expr,
          Dwarf_Small opcode,
          Dwarf_Unsigned vall,
          Dwarf_Unsigned val2,
          Dwarf Error *error)
```

The function dwarf\_add\_expr\_gen() takes an operator specified by opcode, along with up to 2 operands specified by val1, and val2, converts it into the Dwarf representation and appends the bytes to the byte stream being assembled for the location expression represented by expr. The first operand, if present, to opcode is in val1, and the second operand, if present, is in val2. Both the operands may actually be signed or unsigned depending on opcode. It returns the number of bytes in the byte stream for expr currently generated, i.e. after the addition of opcode. It returns DW\_DLV\_NOCOUNT on error.

The function dwarf\_add\_expr\_gen() works for all opcodes except those that have a target address as an operand. This is because it does not set up a relocation record that is needed when target addresses are involved.

#### **5.4.3** dwarf\_add\_expr\_addr()

The function dwarf\_add\_expr\_addr() is used to add the DW\_OP\_addr opcode to the location expression represented by the given Dwarf\_P\_Expr descriptor, expr. The value of the relocatable address is given by address. The symbol to be used for relocation is given by sym\_index, which is the index of the symbol in the Elf symbol table. It returns the number of bytes in the byte stream for expr currently generated, i.e. after the addition of the DW\_OP\_addr operator. It returns DW\_DLV\_NOCOUNT on error.

# 5.4.4 dwarf\_add\_expr\_addr\_b()

The function dwarf\_add\_expr\_addr\_f() is identical to dwarf\_add\_expr\_addr() except that sym\_index() is guaranteed to be large enough that it can contain a pointer to arbitrary data (so the caller can pass in a real elf symbol index, an arbitrary number, or a pointer to arbitrary data). The ability to pass in a pointer through sym\_index() is only usable with DW\_DLC\_SYMBOLIC\_RELOCATIONS.

#### **5.4.5** dwarf\_expr\_current\_offset()

The function dwarf\_expr\_current\_offset() returns the number of bytes currently in the byte stream for the location expression represented by the given W(Dwarf\_P\_Expr descriptor, expr. It returns DW DLV NOCOUNT on error.

#### 5.4.6 dwarf expr into block()

The function dwarf\_expr\_into\_block() returns the address of the start of the byte stream generated for the location expression represented by the given Dwarf\_P\_Expr descriptor, expr. The length of the byte stream is returned in the location pointed to by length. It returns DW\_DLV\_BADADDR on error.

## **5.5** Line Number Operations

These are operations on the .debug\_line section. They provide information about instructions in the program and the source lines the instruction come from. Typically, code is generated in contiguous blocks, which may then be relocated as contiguous blocks. To make the provision of relocation information more efficient, the information is recorded in such a manner that only the address of the start of the block needs to be relocated. This is done by providing the address of the first instruction in a block using the function dwarf\_lne\_set\_address(). Information about the instructions in the block are then added using the function dwarf\_add\_line\_entry(), which specifies offsets from the address of the first instruction. The end of a contiguous block is indicated by calling the function dwarf\_lne\_end\_sequence().

Line number operations do not support DW\_DLC\_SYMBOLIC\_RELOCATIONS.

#### 5.5.1 dwarf\_add\_line\_entry()

The function dwarf\_add\_line\_entry() adds an entry to the section containing information about source lines. It specifies in code\_offset, the offset from the address set using dwarfdwarf\_lne\_set\_address(), of the address of the first instruction in a contiguous block. The source file that gave rise to the instruction is specified by file\_index, the source line number is specified by lineno, and the source column number is specified by column\_number (column numbers begin at 1) (if the source column is unknown, specify 0). file\_index is the index of the source file in a list of source files which is built up using the function dwarf\_add\_file\_decl().

is\_source\_stmt\_begin is a boolean flag that is true only if the instruction at code\_address is the first instruction in the sequence generated for the source line at lineno. Similarly, is\_basic\_block\_begin is a boolean flag that is true only if the instruction at code\_address is the first instruction of a basic block.

It returns 0 on success, and DW\_DLV\_NOCOUNT on error.

#### 5.5.2 dwarf\_lne\_set\_address()

The function <code>dwarf\_lne\_set\_address()</code> sets the target address at which a contiguous block of instructions begin. Information about the instructions in the block is added to <code>.debug\_line</code> using calls to <code>dwarfdwarf\_add\_line\_entry()</code> which specifies the offset of each instruction in the block relative to the start of the block. This is done so that a single relocation record can be used to obtain the final target address of every instruction in the block.

The relocatable address of the start of the block of instructions is specified by offs. The symbol used to

relocate the address is given by symidx, which is normally the index of the symbol in the Elf symbol table.

It returns 0 on success, and DW DLV NOCOUNT on error.

#### 5.5.3 dwarf lne end sequence()

The function dwarf\_lne\_end\_sequence() indicates the end of a contiguous block of instructions. address() should be just higher than the end of the last address in the sequence of instructions. block of instructions, a call to dwarf\_lne\_set\_address() will have to be made to set the address of the start of the target address of the block, followed by calls to dwarf\_add\_line\_entry() for each of the instructions in the block.

It returns 0 on success, and DW\_DLV\_NOCOUNT on error.

## 5.5.4 dwarf\_add\_directory\_decl()

The function dwarf\_add\_directory\_decl() adds the string specified by name to the list of include directories in the statement program prologue of the .debug\_line section. The string should therefore name a directory from which source files have been used to create the present object.

It returns the index of the string just added, in the list of include directories for the object. This index is then used to refer to this string. It returns DW\_DLV\_NOCOUNT on error.

#### 5.5.5 dwarf\_add\_file\_decl()

The function dwarf\_add\_file\_decl() adds the name of a source file that contributed to the present object. The name of the file is specified by name (which must not be the empty string or a null pointer, it must point to a string with length greater than 0). In case the name is not a fully-qualified pathname, it is prefixed with the name of the directory specified by dir\_idx. dir\_idx is the index of the directory to be prefixed in the list builtup using dwarf add directory decl().

time\_mod gives the time at which the file was last modified, and length gives the length of the file in bytes.

It returns the index of the source file in the list built up so far using this function, on success. This index

can then be used to refer to this source file in calls to  $dwarf\_add\_line\_entry()$ . On error, it returns  $DW\_DLV\_NOCOUNT$ .

## 5.6 Fast Access (aranges) Operations

These functions operate on the .debug\_aranges section.

#### **5.6.1** dwarf\_add\_arange()

The function dwarf\_add\_arange() adds another address range to be added to the section containing address range information, .debug\_aranges. The relocatable start address of the range is specified by begin\_address, and the length of the address range is specified by length. The relocatable symbol to be used to relocate the start of the address range is specified by symbol\_index, which is normally the index of the symbol in the Elf symbol table.

It returns a non-zero value on success, and 0 on error.

#### 5.6.2 dwarf\_add\_arange\_b()

The function dwarf\_add\_arange\_b() adds another address range to be added to the section containing address range information, .debug\_aranges.

If end\_symbol\_index is not zero we are using two symbols to create a length (must be DW\_DLC\_SYMBOLIC\_RELOCATIONS to be useful)

begin\_address is the offset from the symbol specified by symbol\_index . offset\_from\_end\_symbol is the offset from the symbol specified by end\_symbol\_index. length is ignored. This begin-end pair will be show up in the relocation array returned by dwarf\_get\_relocation\_info() as a dwarf\_drt\_first\_of\_length\_pair and dwarf\_drt\_second\_of\_length\_pair pair of relocation records. The consuming application will turn that pair into something conceptually identical to

```
.word end_symbol + offset_from_end - \
  ( start_symbol + begin_address)
```

The reason offsets are allowed on the begin and end symbols is to allow the caller to re-use existing labels when the labels are available and the corresponding offset is known (economizing on the number of labels in use). The 'offset\_from\_end - begin\_address' will actually be in the binary

stream, not the relocation record, so the app processing the relocation array must read that stream value into (for example) net\_offset and actually emit something like

```
.word end_symbol - start_symbol + net_offset
```

If end\_symbol\_index is zero we must be given a length (either DW\_DLC\_STREAM\_RELOCATIONS or DW DLC SYMBOLIC RELOCATIONS):

The relocatable start address of the range is specified by begin\_address, and the length of the address range is specified by length. The relocatable symbol to be used to relocate the start of the address range is specified by symbol\_index, which is normally the index of the symbol in the Elf symbol table. The offset\_from\_end\_symbol is ignored.

It returns a non-zero value on success, and 0 on error.

# 5.7 Fast Access (pubnames) Operations

These functions operate on the .debug\_pubnames section.

## **5.7.1** dwarf\_add\_pubname()

The function dwarf\_add\_pubname() adds the pubname specified by pubname\_name to the section containing pubnames, i.e.

.debug\_pubnames. The DIE that represents the function being named is specified by die.

It returns a non-zero value on success, and 0 on error.

#### 5.8 Fast Access (weak names) Operations

These functions operate on the .debug\_weaknames section.

#### **5.8.1** dwarf\_add\_weakname()

The function dwarf\_add\_weakname() adds the weak name specified by weak\_name to the section containing weak names, i.e.

.debug\_weaknames. The DIE that represents the function being named is specified by die.

It returns a non-zero value on success, and 0 on error.

## **5.9 Static Function Names Operations**

The .debug\_funcnames section contains the names of static function names defined in the object, and also the offsets of the DIEs that represent the definitions of the functions in the .debug\_info section.

# **5.9.1** dwarf\_add\_funcname()

The function dwarf\_add\_funcname() adds the name of a static function specified by func\_name to the section containing the names of static functions defined in the object represented by dbg. The DIE that represents the definition of the function is specified by die.

It returns a non-zero value on success, and 0 on error.

# 5.10 File-scope User-defined Type Names Operations

The .debug\_typenames section contains the names of file-scope user-defined types in the given object, and also the offsets of the DIEs that represent the definitions of the types in the .debug\_info section.

## **5.10.1** dwarf\_add\_typename()

The function dwarf\_add\_typename() adds the name of a file-scope user-defined type specified by type\_name to the section that contains the names of file-scope user-defined type. The object that this section belongs to is specified by dbg. The DIE that represents the definition of the type is specified by die.

It returns a non-zero value on success, and 0 on error.

#### 5.11 File-scope Static Variable Names Operations

The .debug\_varnames section contains the names of file-scope static variables in the given object, and also the offsets of the DIEs that represent the definition of the variables in the .debug\_info section.

#### **5.11.1** dwarf\_add\_varname()

The function dwarf\_add\_varname() adds the name of a file-scope static variable specified by

var\_name to the section that contains the names of file-scope static variables defined by the object represented by dbg. The DIE that represents the definition of the static variable is specified by die.

It returns a non-zero value on success, and 0 on error.

#### 5.12 Macro Information Creation

All strings passed in by the caller are copied by these functions, so the space in which the caller provides the strings may be ephemeral (on the stack, or immediately reused or whatever) without this causing any difficulty.

#### 5.12.1 dwarf def macro()

Adds a macro definition. The name argument should include the parentheses and parameter names if this is a function-like macro. Neither string should contain extraneous whitespace. dwarf\_def\_macro() adds the mandated space after the name and before the value in the output DWARF section(but does not change the strings pointed to by the arguments). If this is a definition before any files are read, lineno should be 0. Returns DW\_DLV\_ERROR and sets error if there is an error. Returns DW\_DLV\_OK if the call was successful.

#### **5.12.2** dwarf\_undef\_macro()

Adds a macro un-definition note. If this is a definition before any files are read, lineno should be 0. Returns DW\_DLV\_ERROR and sets error if there is an error. Returns DW\_DLV\_OK if the call was successful.

#### 5.12.3 dwarf\_start\_macro\_file()

fileindex is an index in the .debug\_line header: the index of the file name. See the function dwarf\_add\_file\_decl(). The lineno should be 0 if this file is the file of the compilation unit source itself (which, of course, is not a #include in any file). Returns DW\_DLV\_ERROR and sets error if there is an error. Returns DW\_DLV\_OK if the call was successful.

#### 5.12.4 dwarf\_end\_macro\_file()

Returns DW\_DLV\_ERROR and sets error if there is an error. Returns DW\_DLV\_OK if the call was successful.

#### 5.12.5 dwarf\_vendor\_ext()

```
int dwarf_vendor_ext(Dwarf_P_Debug dbg,
    Dwarf_Unsigned constant,
    char * string,
    Dwarf Error* error);
```

The meaning of the constant and thestring in the macro info section are undefined by DWARF itself, but the string must be an ordinary null terminated string. This call is not an extension to DWARF. It simply enables storing macro information as specified in the DWARF document. Returns DW\_DLV\_ERROR and sets error if there is an error. Returns DW\_DLV\_OK if the call was successful.

## 5.13 Low Level (.debug\_frame) operations

These functions operate on the .debug\_frame section. Refer to libdwarf.h for the register names and register assignment mapping. Both of these are necessarily machine dependent.

#### 5.13.1 dwarf\_new\_fde()

The function dwarf\_new\_fde() returns a new Dwarf\_P\_Fde descriptor that should be used to build a complete FDE. Subsequent calls to routines that build up the FDE should use the same Dwarf\_P\_Fde descriptor.

It returns a valid Dwarf\_P\_Fde descriptor on success, and DW\_DLV\_BADADDR on error.

## **5.13.2** dwarf\_add\_frame\_cie()

The function dwarf\_add\_frame\_cie() creates a CIE, and returns an index to it, that should be used to refer to this CIE. CIEs are used by FDEs to setup initial values for frames. The augmentation string for the CIE is specified by augmenter. The code alignment factor, data alignment factor, and the return address register for the CIE are specified by code\_align, data\_align, and ret\_addr\_reg

respectively. init\_bytes points to the bytes that represent the instructions for the CIE being created, and init\_bytes\_len specifies the number of bytes of instructions.

There is no convenient way to generate the <code>init\_bytes</code> stream. One just has to calculate it by hand or separately generate something with the correct sequence and use dwarfdump -v and elfdump -h and some kind of hex dumper to see the bytes. This is a serious inconvenience!

It returns an index to the CIE just created on success. On error it returns DW DLV NOCOUNT.

## **5.13.3** dwarf\_add\_frame\_fde()

The function dwarf\_add\_frame\_fde() adds the FDE specified by fde to the list of FDEs for the object represented by the given dbg. die specifies the DIE that represents the function whose frame information is specified by the given fde. cie specifies the index of the CIE that should be used to setup the initial conditions for the given frame.

It returns an index to the given fde.

#### 5.13.4 dwarf add frame fde b()

This function is like dwarf\_add\_frame\_fde() except that dwarf\_add\_frame\_fde\_b() has new arguments to allow use with DW\_DLC\_SYMBOLIC\_RELOCATIONS.

The function dwarf\_add\_frame\_fde\_b() adds the FDE specified by fde to the list of FDEs for the object represented by the given dbg. die specifies the DIE that represents the function whose frame information is specified by the given fde. cie specifies the index of the CIE that should be used to setup the initial conditions for the given frame. virt\_addr represents the relocatable address at which the code for the given function begins, and sym\_idx gives the index of the relocatable symbol to be used to relocate this address (virt\_addr that is). code\_len specifies the size in bytes of the machine instructions for the given function.

```
If sym_idx_of_end is zero (may be DW_DLC_STREAM_RELOCATIONS or DW_DLC_SYMBOLIC_RELOCATIONS):
```

virt\_addr represents the relocatable address at which the code for the given function begins, and sym\_idx gives the index of the relocatable symbol to be used to relocate this address (virt\_addr that is). code\_len specifies the size in bytes of the machine instructions for the given function. sym\_idx\_of\_end and offset\_from\_end\_sym are unused.

If sym\_idx\_of\_end is non-zero (must be DW\_DLC\_SYMBOLIC\_RELOCATIONS to be useful):

virt\_addr is the offset from the symbol specified by sym\_idx. offset\_from\_end\_sym is the offset from the symbol specified by sym\_idx\_of\_end. code\_len is ignored. This begin-end pair will be show up in the relocation array returned by dwarf\_get\_relocation\_info() as a dwarf\_drt\_first\_of\_length\_pair and dwarf\_drt\_second\_of\_length\_pair pair of relocation records. The consuming application will turn that pair into something conceptually identical to

```
.word end_symbol + begin - \
  ( start_symbol + offset_from_end)
```

The reason offsets are allowed on the begin and end symbols is to allow the caller to re-use existing labels when the labels are available and the corresponding offset is known (economizing on the number of labels in use). The 'offset\_from\_end - begin\_address' will actually be in the binary stream, not the relocation record, so the app processing the relocation array must read that stream value into (for example) net\_offset and actually emit something like

```
.word\ end\_symbol\ -\ start\_symbol\ +\ net\_offset
```

It returns an index to the given fde.

On error, it returns DW\_DLV\_NOCOUNT.

## 5.13.5 dwarf\_add\_frame\_info\_b()

```
Dwarf Unsigned dwarf add frame info b(
        Dwarf_P_Debug
                        dbq,
        Dwarf_P_Fde
                        fde,
        Dwarf_P_Die
                        die,
        Dwarf Unsigned cie,
        Dwarf_Addr
                        virt_addr,
        Dwarf Unsigned code len,
        Dwarf Unsigned sym idx,
        Dwarf_Unsigned end_symbol_index,
        Dwarf_Addr
                        offset_from_end_symbol,
        Dwarf_Signed
                        offset_into_exception_tables,
        Dwarf Unsigned
                        exception table symbol,
        Dwarf Error*
                        error)
```

The function dwarf\_add\_frame\_fde() adds the FDE specified by fde to the list of FDEs for the object represented by the given dbg. die specifies the DIE that represents the function whose frame information is specified by the given fde. cie specifies the index of the CIE that should be used to setup

the initial conditions for the given frame. offset\_into\_exception\_tables specifies the offset into .MIPS.eh\_region elf section where the exception tables for this function begins. exception\_table\_symbol gives the index of the relocatable symbol to be used to relocate this offset.

If end\_symbol\_index is not zero we are using two symbols to create a length (must be DW\_DLC\_SYMBOLIC\_RELOCATIONS to be useful)

virt\_addr is the offset from the symbol specified by sym\_idx. offset\_from\_end\_symbol is the offset from the symbol specified by end\_symbol\_index. code\_len is ignored. This begin-end pair will be show up in the relocation array returned by dwarf\_get\_relocation\_info() as a dwarf\_drt\_first\_of\_length\_pair and dwarf\_drt\_second\_of\_length\_pair pair of relocation records. The consuming application will turn that pair into something conceptually identical to

```
.word end_symbol + offset_from_end_symbol - \
  ( start_symbol + virt_addr)
```

The reason offsets are allowed on the begin and end symbols is to allow the caller to re-use existing labels when the labels are available and the corresponding offset is known (economizing on the number of labels in use). The 'offset\_from\_end - begin\_address' will actually be in the binary stream, not the relocation record, so the app processing the relocation array must read that stream value into (for example) net\_offset and actually emit something like

```
.word end_symbol - start_symbol + net_offset
```

If end\_symbol\_index is zero we must be given a code\_len value (either DW\_DLC\_STREAM\_RELOCATIONS or DW\_DLC\_SYMBOLIC\_RELOCATIONS ):

The relocatable start address of the range is specified by virt\_addr, and the length of the address range is specified by code\_len. The relocatable symbol to be used to relocate the start of the address range is specified by symbol\_index, which is normally the index of the symbol in the Elf symbol table. The offset\_from\_end\_symbol is ignored.

It returns an index to the given fde.

On error, it returns DW\_DLV\_NOCOUNT.

### 5.13.6 dwarf\_add\_frame\_info()

The function dwarf\_add\_frame\_fde() adds the FDE specified by fde to the list of FDEs for the object represented by the given dbg. die specifies the DIE that represents the function whose frame information is specified by the given fde. cie specifies the index of the CIE that should be used to setup the initial conditions for the given frame. virt\_addr represents the relocatable address at which the code for the given function begins, and sym\_idx gives the index of the relocatable symbol to be used to relocate this address (virt\_addr that is). code\_len specifies the size in bytes of the machine instructions for the given function. offset\_into\_exception\_tables specifies the offset into .MIPS.eh\_region elf section where the exception tables for this function begins. exception\_table\_symbol gives the index of the relocatable symbol to be used to relocate this offset.

It returns an index to the given fde.

#### 5.13.7 dwarf\_fde\_cfa\_offset()

The function dwarf\_fde\_cfa\_offset() appends a DW\_CFA\_offset operation to the FDE, specified by fde, being constructed. The first operand of the DW\_CFA\_offset operation is specified by regP. The register specified should not exceed 6 bits. The second operand of the DW\_CFA\_offset operation is specified by offset.

```
It returns the given fde on success.
```

It returns DW DLV BADADDR on error.

# 5.13.8 dwarf\_add\_fde\_inst()

The function dwarf\_add\_fde\_inst() adds the operation specified by op to the FDE specified by fde. Upto two operands can be specified in val1, and val2. Based on the operand specified Libdwarf decides how many operands are meaningful for the operand. It also converts the operands to

the appropriate datatypes (they are passed to dwarf\_add\_fde\_inst as Dwarf\_Unsigned).

It returns the given fde on success, and DW\_DLV\_BADADDR on error.

# A Producer Library Interface to DWARF

David Anderson

# **ABSTRACT**

This document describes an interface to a library of functions to create DWARF debugging information entries and DWARF line number information. It does not make recommendations as to how the functions described in this document should be implemented nor does it suggest possible optimizations.

The document is oriented to creating DWARF version 2. Support for creating DWARF3 is intended but such support is not yet fully present.
